Question: *What is the difference between a horizontal and a vertical navigation menu?*

- **Answer:** A horizontal navigation menu places link items side-by-side in a row (commonly used in headers across desktop screens), whereas a vertical navigation menu stacks link items on top of each other in a column (commonly used in sidebars or mobile menus).

Question: *What do `justify-content` and `flex-wrap` each control?*

- **Answer:** `justify-content` controls the alignment and spacing of flex items along the main axis (e.g., centering or spreading links evenly). `flex-wrap` controls whether flex items are forced onto a single line (`nowrap`) or allowed to wrap onto multiple lines (`wrap`) when space is limited.

Question: *What is the difference between `position: relative` and `position: absolute` in your submenu?*

- **Answer:** `position: relative` on the parent `<li>` establishes it as a reference positioning container without removing it from normal flow. `position: absolute` on the `.submenu` removes the dropdown from normal document flow and positions it directly relative to that parent item without disrupting other layout elements.

Question: *What changed in the appearance of your existing website after you added navigation?*

- **Answer:** A structured, responsive header navigation bar was introduced with customized link highlights for active pages, clear visual focus/hover indicators, and a hidden dropdown submenu that displays seamlessly when hovered or focused.

Question: *What problem did you find during testing, and how did you correct it?*

- **Answer:** During keyboard navigation testing, the submenu links were not remaining visible when tabbing through them. This was corrected by adding the `.has-submenu:focus-within > .submenu` selector to ensure the dropdown stays expanded whenever any child link receives keyboard focus.
